4$$

I is the highest factor.

$$gcd(23,5) \Rightarrow gcd(18,5) \Rightarrow gcd(13,5) = gcd(8,5) = gcd(3,5)$$

# We are doing repeated Subtraction.

$$gcd(24,16) \Rightarrow gcd(24\% 16,16) \Rightarrow gcd(8,16) \Rightarrow gcd(8,16) \Rightarrow gcd(8,16) \Rightarrow gcd(8,16)$$

From properties: 
$$gcd(A,B) = gcd(B,A) = gcd(A,B,B)$$

$$gcd(A,B) = gcd(B,A,B)$$
(recursion)

$$gcd(24,16) \Rightarrow gcd(16,8) \Rightarrow gcd(20) = 8$$
  
 $gcd(14,24) \Rightarrow gcd(24,14) \Rightarrow gcd(14,10) = gcd(10,4) = gcd(4,2)$   
 $= gcd(2,0) = 2$ .  
 $gcd(0,10) \Rightarrow gcd(0,0) = 10$ 

## Pseudocode:

1/ ASSUmption: To ealc & return gcd(a,b) int gcd(int a, int b) { if(b==0) { return a } return ged (b, a°l.b) return according to an TC: O(log (min (a, b))) main ( ) {

gcd ( | a|, | b|)

Proof of God TC:

0(log (min (a, b)))

First notice that for arbitrary integers x, y such that  $x \ge y$ , we get  $x \% y \le \frac{x}{2}$ . This is due to:

- x % y < y
- $x \% y \leq x y$

During the process of the algorithm, suppose we have our current integers  $a, b, a \ge b$ . In the following 2 steps, both of them are being taken modulo a value not greater than them. Using the above observation, after these 2 steps we get 2 integers at most  $\frac{a}{2}$ ,  $\frac{b}{2}$ respectively. Once one of them becomes 0 the algorithm terminates, so the algorithm terminates in at most  $2\log_2(\min(a,b))$ , which implies  $\mathcal{O}(\log(\min(a,b)))$ .

In School: gcd(14,24)

Prime Numbers: No. with only 2 factors (1 & itself) 5, 9, 11, 1 L) 2 different factors Count factors idea: Brute force > != 2: not prime! bool is Prime (int n) } C = 0 Tc: O(n) for (i=1°, i <= n°, i++) } if (nº/oi ==0) {c++3 SC: 0(1) if (c==2) { return true } else ? return false ?
